Abstract

The upper Sustut River steelhead (*Oncorhynchus mykiss*) population was enumerated from July 27 to September 30, 2001, using a floating PVC fence. The first steelhead migrated past the fence on August 15 and by September 30, a total of 756 steelhead had been released upstream. This value was defined as the upper Sustut River steelhead index for 2001. An additional 42 steelhead were observed downstream of the fence on September 30 making the estimated spawning escapement to the upper Sustut River 798 steelhead. The population index for 2001 was the second highest on record while the spawning escapement was 77 percent of the estimated carrying capacity (1036) for the upper Sustut system (Tautz *et al.* 1992). Between July 27 and September 30, a total of 1639 chinook salmon (*O. tshawytscha*), 1257 sockeye salmon (*O. nerka*), 9 coho salmon (*O. kisutch*), 30 bull trout (*Salvelinus confluentus*), 0 resident rainbow trout (*O. mykiss*) and 24 Rocky Mountain whitefish (*Prosopium williamsoni*) were counted passing upstream of the fence.

Eighteen steelhead tagged at the upper Sustut River fence in 1999 were recaptured in 2001 indicating that a minimum of 2.5 percent of the 1999 run returned as potential repeat spawners. While the percentage of repeat spawners was above the long-term average (1.4%), the growth between spawning events (6.5 cm) was below the average (7.5 cm). Three steelhead tagged at the fence in 1998 were recaptured in 2001 indicating that a minimum of 0.2 percent of the 1998 run returned as potential repeat spawners.

Age analysis from scales revealed that all the adult steelhead had at least two marine annuli, and repeat spawners made up 6.1 percent of the sample. The most prevalent age was 4.3+ (46.9%) followed by 4.2+ (24.5%). The majority of the steelhead spent four years in freshwater (86.6%), while 6.7% had a three-year freshwater age, and 6.7 percent had a five-year freshwater age.

The ratio of female to male steelhead was 1.63:1. The average fork length of males and females was 86.4 and 77.1 cm, respectively. A total of 12.8 percent of all steelhead handled at the fence exhibited gillnet marks. This falls in the middle portion of historical values, which have ranged from 2 to 23 percent and averaged 11.7 percent. Female steelhead exhibited a higher gillnet mark rate than males (14.5 and 10.1 percent, respectively). Further, gillnet marked males and females were significantly smaller than those without gillnet marks.

With the addition of the 2001 data point, the upper Sustut steelhead population index was no longer correlated with the cumulative Tyee test fishery index to August 10.

1.0 Introduction

The upper Sustut River steelhead (*Oncorhynchus mykiss*) stock has been used as an index population for early run summer steelhead in the Skeena Region since 1986 (Spence *et al.* 1990; Bustard 1993; Saimoto 1994; Saimoto 1995; Parken and Morten 1996; Parken *et al.* 1997; Williamson 1998, 1999a, 1999b, 2000; Diewert 2000). Early run steelhead stocks are of special concern for fisheries managers as their migration timing coincides with intense commercial fisheries for sockeye (*O. nerka*) and pink (*O. gorbuscha*) salmon where they are often captured incidentally (Ward *et al.* 1993; Cox-Rogers 1994). The resulting impact on the spawning populations can be significant and potentially detrimental to the long term viability of these important stocks. Annual enumeration of the upper Sustut River steelhead stock provides yearly population index values and time series data that demonstrate trends in the abundance of all early run Skeena steelhead.

The objectives of the 2001 enumeration program were:

1. to index the upper Sustut River steelhead population,
2. to determine the number of previously tagged steelhead, by sex, that returned in 2001, and to calculate the growth rate for these repeat spawners,
3. to examine the sex ratio and size distribution of steelhead throughout the run,
4. to examine the effect of water height and temperature on steelhead migration,
5. to examine the number of gillnet marked steelhead and the distribution of gillnet marked fish throughout the run,
6. to examine the relative run timing of male and female steelhead,
7. to examine the effect of adding the 2001 data to the regression relationship between the upper Sustut River steelhead index and the cumulative Tyee test fishery index, and
8. to further assess the selectivity of angling as a sampling method for steelhead.

2.0 Study Area

The Sustut River is located in north central British Columbia and is a tributary to the upper Skeena River (Figure 1). Originating in the Omenica Mountains approximately 220 km north of Smithers, B.C., the Sustut River flows for 8 km northwest from Sustut and Mud lakes where it joins Johanson Creek near the main spawning area for upper Sustut steelhead (Bustard 1993). The

river then flows 3 km west to its confluence with Moosevale Creek before turning southwest for approximately 100 km and flowing into the Skeena River. The Sustut River drains approximately 3,574 km² and has seven main tributaries: Birdflat Creek, Bear River, Asitka River, Red Creek, Two Lake Creek, Moosevale Creek and Johanson Creek. Fish species known to inhabit the upper Sustut River include steelhead, chinook salmon (*O. tshawytscha*), sockeye salmon, coho salmon (*O. kisutch*), bull trout (*Salvelinus confluentus*), Dolly Varden char (*S. malma*), Rocky Mountain whitefish (*Prosopium williamsoni*), Bustard 1993; Saimoto 1994; Saimoto 1995) and burbot (*Lota lota*)¹. The physical area that defines the upper Sustut River steelhead population is the Sustut River upstream of the Moosevale Creek confluence including Johanson Creek and Sustut and Johanson lakes (Spence *et al.* 1990, Figure 1). The physical area that defines the lower Sustut River steelhead population is the Sustut River downstream of the Bear River confluence, including Bear River and Bear Lake (Spence *et al.* 1990; Figure 1).

3.0 Methods

3.1 Steelhead Enumeration

A floating fish counting fence constructed from 3.8 cm PVC pipe was placed in the Sustut River, 500 m upstream of the confluence with Moosevale Creek and 70 km upstream of the confluence with the Bear River (Figures 2, 3). The fence was operated between July 27 and September 30. On September 17, 2000, a breach in the fence occurred when extremely high flows and heavy debris load resulted in the cable that secured the fence to the stream bed giving way. The cable was replaced during fence installation in 2001. Also, a new aluminum trap box was fabricated to replace the aging wooden structure, which had been in use for several years.

The total count of steelhead migrating past the fence has been defined as the upper Sustut River steelhead index. Fish holding between the fence and the Moosevale Creek confluence pool were counted during a visual survey on September 30 by two streamside observers using polarized sunglasses. The sum of the upper Sustut River steelhead index and the visual survey count of the section of the river immediately downstream of the fence equal the total escapement for the upper Sustut River steelhead population.

The fence was inspected daily for debris accumulation and openings passable to fish. Debris was removed and repairs made as necessary. The fence trap box was checked in the morning and evening during low levels of fish

¹ In August, 1999 a single juvenile burbot (<10 cm fork-length) was found in a beaver impoundment by Ministry Staff on the Sustut River approximately 800 meters upstream of its confluence with Johanson Creek.

migration and was checked more frequently during heavier migration. It was observed that the handling of fish would often halt or delay migration for considerable periods. Therefore, counting and tagging sessions were limited to avoid delaying fish migration. Past fence modifications implemented to reduce stress and mortality caused by the original fence design and handling procedures were used again in 2001 (Williamson 1999b).

Experienced personnel, using the visual characteristics described in Scott and Crossman (1973) and McPhail and Carveth (1994), identified all fish passing the fence to species. All steelhead were tagged on the right side immediately below the dorsal fin with yellow, uniquely numbered, t-bar anchor tags and measured for nose-fork length to the nearest 0.5 cm. Sex, gillnet marks, scars, wounds and general condition were recorded for each fish. Adipose tissue was collected from 100 steelhead to aid in stock identification and molecular genetic comparisons between upper and lower Sustut steelhead and resident rainbow trout populations. A sample of 5 scales, taken mid-laterally between the dorsal and anal fins, was collected from the same 100 steelhead to determine the age structure of the population. All fish mortalities resulting from fence operation or handling by personnel, as well as post spawn carcasses, were examined and sampled. All other species of fish encountered at the fence were enumerated and sub-sampled for genetic stock identification and aging.

3.2 Steelhead Recaptures

Sex, fork length and the presence of gillnet marks or predator scars were recorded for previously tagged steelhead (identified by tag presence, or unhealed scar in the tag position). Tag colour and number were recorded and compared to the Ministry of Environment, Lands and Parks, Skeena Region, TAGS database to determine original tagging location and date. Fork lengths of recaptured fish were compared between tagging periods to determine growth rates.

3.3 Steelhead Migration and Physical Data

Stream temperatures were recorded once daily by personnel using a Brannon minimum-maximum thermometer. Water levels were recorded in the morning and the evening using an instream staff-gauge. Air temperature and weather conditions were also recorded daily. Maximum daily water temperature and level were examined against steelhead migration by graphical and statistical methods to determine if these physical factors influenced migration patterns.

3.4 Steelhead Length Distributions

Steelhead nose-fork lengths were measured to the nearest 0.5 cm. using

an EVAZOTE (blue camping foam) lined measuring tray. The nose-fork lengths of male and female steelhead were compared graphically using length frequency histograms and statistically using Student's t-test (Zar 1984).

3.5 Steelhead Gillnet Marks

The presence of gillnet marks was recorded for all steelhead. The cumulative daily percentage of steelhead with gillnet marks was compared with the cumulative total number of steelhead for the duration of the run. The mean nose-fork lengths of gillnet marked and unmarked steelhead were compared for each sex (Student's t-test). Temporal trends in the gillnet mark rate were examined by pooling and plotting the percent of gill net marked steelhead by week.

3.6 Male and Female Steelhead Run Timing

The run timing of male and female steelhead was examined by plotting cumulative percent male and female steelhead by date over the duration of fence operation. Further, time series histograms of male and female migration timing were plotted and compared using Student's t-test. The date of first arrival and mean migration date passed the fence for male and female steelhead was also compared.

3.7 Upper Sustut River and Tyee Test Fishery Indices

The cumulative steelhead index at the Tyee test fishery has been used to indicate the relative abundance of steelhead and salmon migrating into the Skeena River (Cox-Rogers and Jantz 1993; Ward *et al.* 1993; Cox-Rogers 1994; Koski *et al.* 1995; Labelle *et al.* 1995). The cumulative steelhead index to August 10 is considered to indicate the relative abundance of early run Skeena River steelhead (upper Sustut River steelhead). This date was chosen as it was the last date that tagged upper Sustut River steelhead were observed in the Tyee test fishery (Parken *et al.* 1997).

In 1996, the relative abundance of upper Sustut River steelhead was standardized into a population index to reduce the variability resulting from the different enumeration methods (Parken *et al.* 1997). This index was defined as the total number of steelhead counted through the upper Sustut River fence to September 30. Parken *et al.* (1997) found that the August 10 cumulative Tyee steelhead index correlated positively with and was a significant predictor of the Upper Sustut steelhead index. This year, the 2001 data point was added to the regression analysis to determine if the August 10 Tyee test fishery index continued to be a significant predictor of the upper Sustut Steelhead population index.

3.8 Steelhead Angling Selectivity

Steelhead were angled from a section of the river downstream of the enumeration fence. Angling techniques were identical to those utilized in stock assessment studies carried out by Ministry of Environment, Fisheries Branch, staff (e.g. Parken and Atagi 1998). All steelhead were captured using roe on barbed hooks. Fish were landed and placed in a V shaped, foam lined tagging tray with a metre stick recessed in one side. Sex, nose-fork length to the nearest 0.5 cm, gillnet marks, hooking location, scars and the general condition of each fish were recorded. A white, uniquely numbered t-bar anchor tag was applied to the right side below the dorsal fin before release and the release condition noted (1=swam away quickly, 2=swam away slowly, 3=required ventilation).

The nose-fork lengths of male and female steelhead in the fence and angled samples were compared graphically using length-frequency histograms and statistically using Student's t-test. Also, the sex ratio of the fence and angled samples were compared statistically using chi-square tests.

Post angling behavior was assessed by comparing the number of days between angling capture and arrival at the fence for males and females using Student's t-test. Also, to assess the effect of size on post angling behavior, the lengths of angled steelhead that arrived at the fence were compared to those that did not migrate past the fence using Student's test.

4.0 Results

4.1 Steelhead Enumeration

Between August 15 and September 30, 756 steelhead migrated through the upper Sustut River fence (fence tagged recaptures removed) (Appendix Tables 2, 6). This value was defined as the upper Sustut River steelhead index for 2001 (Table 1). An additional 42 steelhead were observed between the fence and the Moosevale Creek confluence pool on September 30. Assuming no additional migration from downstream of Moosevale Creek after the visual survey was completed, the estimated spawning escapement for the 2001 upper Sustut River steelhead run was 798 fish.

The first steelhead migrated through the fence on August 15 and by September 16, 50% of the run had passed (Figure 4; Table 1). In order to provide a historical context for the 2001 data, the annual dates of 50% migration along with the corresponding total index values are presented in Table 1 for the years 1994 to 2001. Information prior to 1994 was not included due to variability in enumeration methodology that existed during this period.

The observed handling mortality at the fence was 1.9% (14 steelhead) (Appendix Table 1). The majority of these fish exhibited severe head fungus that may be partially attributed to the new net pen.

Table 1. Dates when 50% of steelhead migrated through the fence and the total index by year.

Between July 27 and September 30, 1639 chinook salmon, 1257 sockeye salmon, 9 coho salmon, 30 bull trout, 0 resident rainbow trout and 24 Rocky Mountain whitefish migrated through the fence (Appendix Tables 2, 3).

4.2 Steelhead Recaptures

Eighteen steelhead (14 female, 4 male) tagged at the Sustut River fence in 1999 were recaptured in 2001 (Table 2). Growth from the date of initial tagging to the date of recapture ranged from 1.2 to 11.6 cm and averaged 6.5

cm. The timing of arrival at the fence for these fish was later in 2001 than in 1999 by an average of 5 days. Three steelhead tagged at the Sustut River fence in 1998 were recaptured in 2001 (Table 2). Growth from the date of initial tagging to the date of recapture ranged from 4.7 cm to 16.2 cm and averaged 12.1 cm. The timing of arrival at the fence for these fish was later in 2001 than in 1998 by an average of 3 days.

A total of 731 steelhead were tagged at the fence in 1999. The 18 fish recaptured in 2001 indicate that a minimum of 2.5% of the 1999 run returned as potential repeat spawners in 2001. A total of 1064 steelhead were tagged at the

fence in 1998. The 3 fish recaptured in 2001 indicate that a minimum of 0.3% of the 1998 run returned as potential repeat spawners in 2001.

4.3 Steelhead Migration and Physical Data

Maximum daily water temperature and staff gauge height were plotted with steelhead migration through the fence (Figures 5, 6). While temperature fluctuation appeared to coincide with increased migration, statistical analysis indicated that neither water temperature nor river level was significantly correlated with steelhead movement past the fence (r values: temperature = 0.2448, level=0.0601; $p=0.05$).

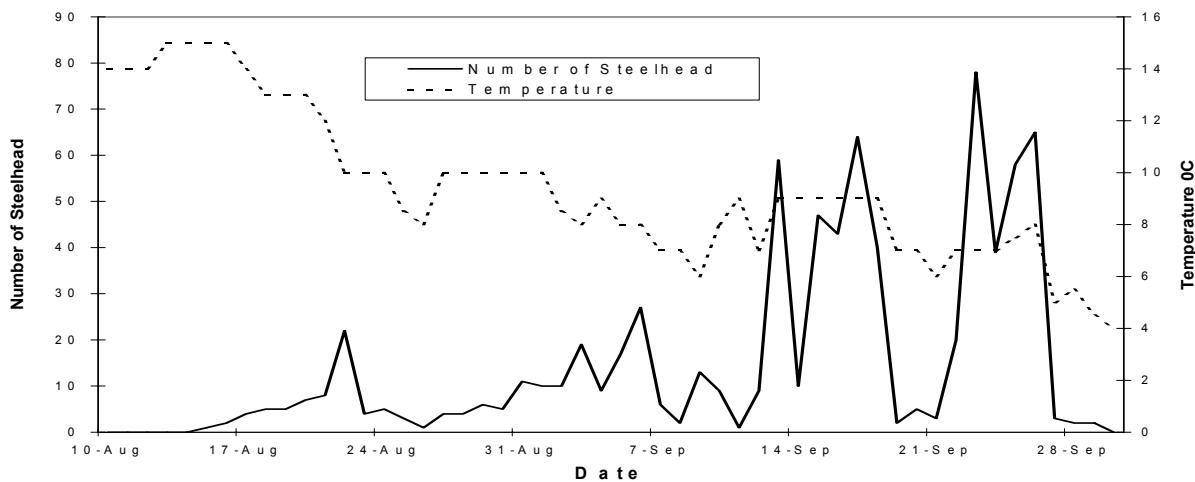

Figure 5. Daily maximum water temperatures and the number of steelhead migrating past the fence.

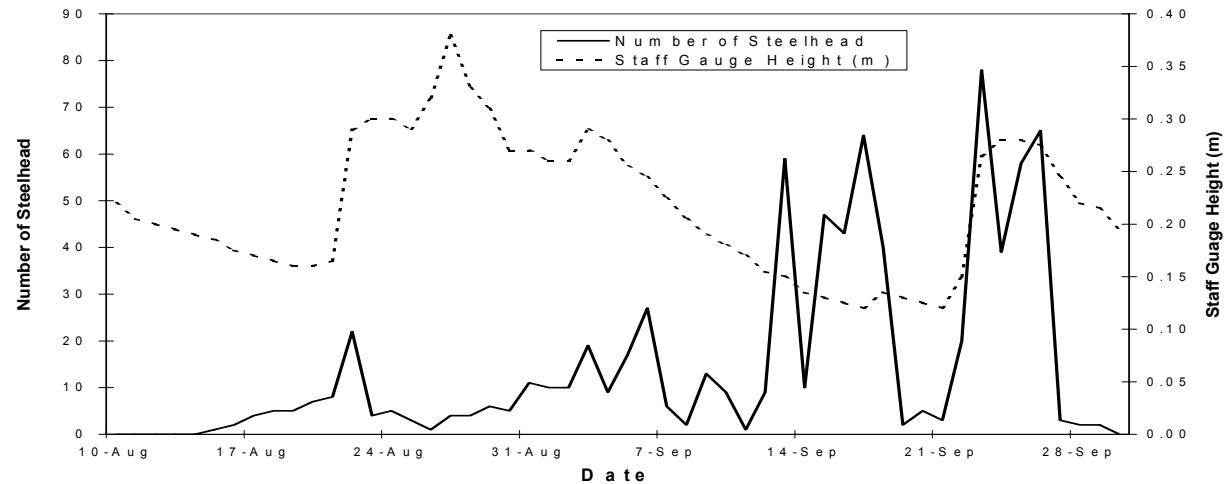

Figure 6. Daily staff gauge height and the number of steelhead migrating past the fence.

All environmental data along with a description of daily weather conditions are presented in Appendix Table 4. Daily minimum and maximum water temperatures are shown graphically in Appendix Figure 1.

4.4 Steelhead Length Distributions by Sex

Of the 756 steelhead handled at the fence, 288 (38.1 %) were males and 468 (61.9 %) were females making the ratio of female to male steelhead 1.62:1. The mean nose-fork lengths of male and female steelhead were 86.4 and 77.1 cm, respectively. The percent of the total number of steelhead measured at the fence was plotted by 2 cm increments of nose-fork length for each sex (Figure 7). Statistical analysis revealed that male steelhead were significantly larger than female steelhead (Students t-test: $t= 21.8633$; $p < 0.05$).

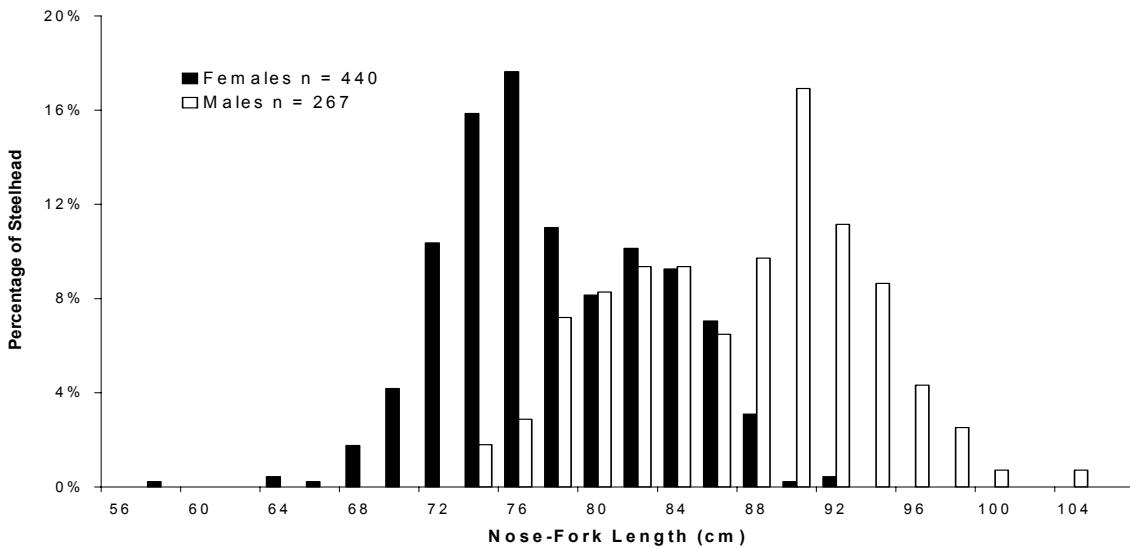

Figure 7. Percentage of male and female steelhead by 2 cm categories of nose-fork length.

4.5 Steelhead Gillnet Marks

Gillnet marks were present on 12.6 % of all steelhead that migrated past the fence. The daily cumulative percentage of gillnet marked steelhead was plotted by date along with cumulative total steelhead (Figure 8). This figure indicates that cumulative gillnet marks remained at zero until August 30th and then increased as the program progressed. This trend became more evident when the percent of gillnet marked steelhead was pooled and plotted by statistical week (statistical week definitions are outlined in Appendix Table 5) (Figure 9). Weekly gillnet mark rates ranged from a low of 0% in statistical weeks 8-2 and 8-3 to a high of 20.2% in statistical week 9-4.

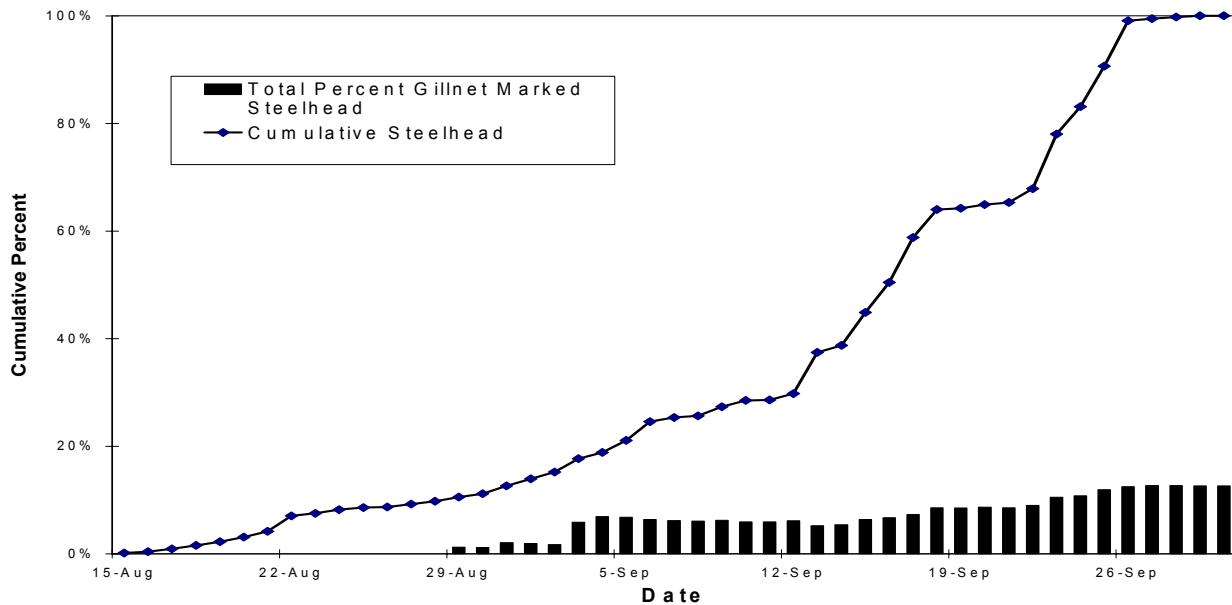

Figure 8. Daily cumulative total gillnet marked steelhead and daily cumulative total steelhead.

A total of 10.1 % of male steelhead and 14.5 % of female steelhead examined at the fence exhibited gillnet marks. These values are higher than those reported for males and females in 1999 (6.1 and 9.9%, respectively; Williamson 2000) but slightly lower than 2000 values (10.6 and 16.2%, for males and females, respectively; Diewert 2000). Gillnet marked males were significantly smaller than unmarked males (mean = 83.5 cm and 86.7 cm, respectively; Students t-test: $t=2.7003$, $p>0.05$). The same was true for net marked and unmarked females (mean = 75.3 cm and 77.4 cm, respectively; Students t-test: $t=3.0647$, $p>0.05$).

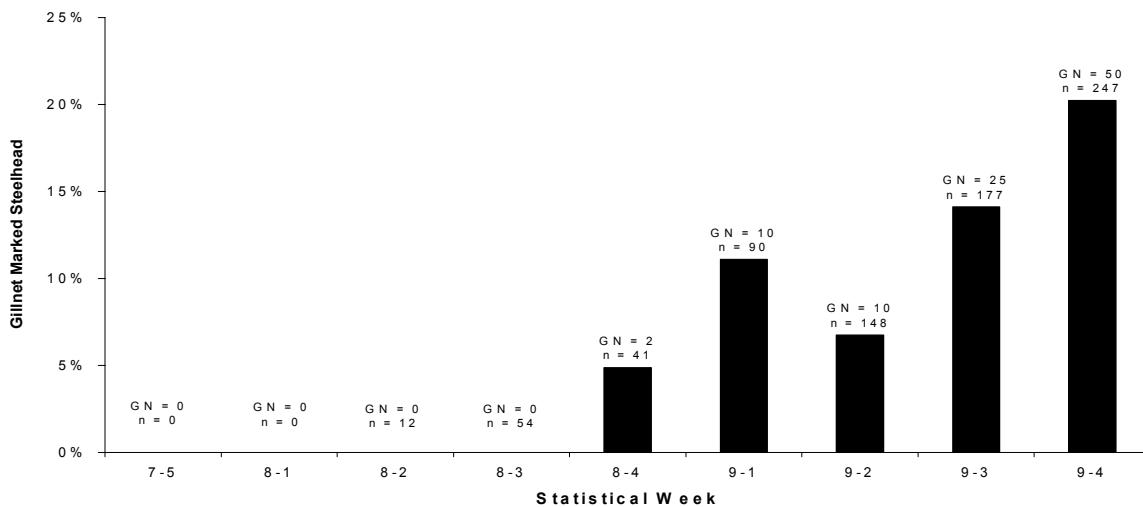

Figure 9. Percent of steelhead with gillnet marks by statistical week. GN = the number of gillnet marked steelhead and n = the total number of steelhead handled each week.

4.6 Male and Female Steelhead Run Timing

The first male steelhead passed through the fence on August 15 while the first female steelhead arrived the following day (August 16). The median migration date for males and females was September 16. The plot of daily cumulative percentage of fish arriving at the fence for both sexes reveals a similar pattern for males and females (Figure 10). Also, when time series histograms were compared, there was no significant difference in the timing of migration past the fence for males and females (Students t-test: $t=1.7517$, $p<0.05$).

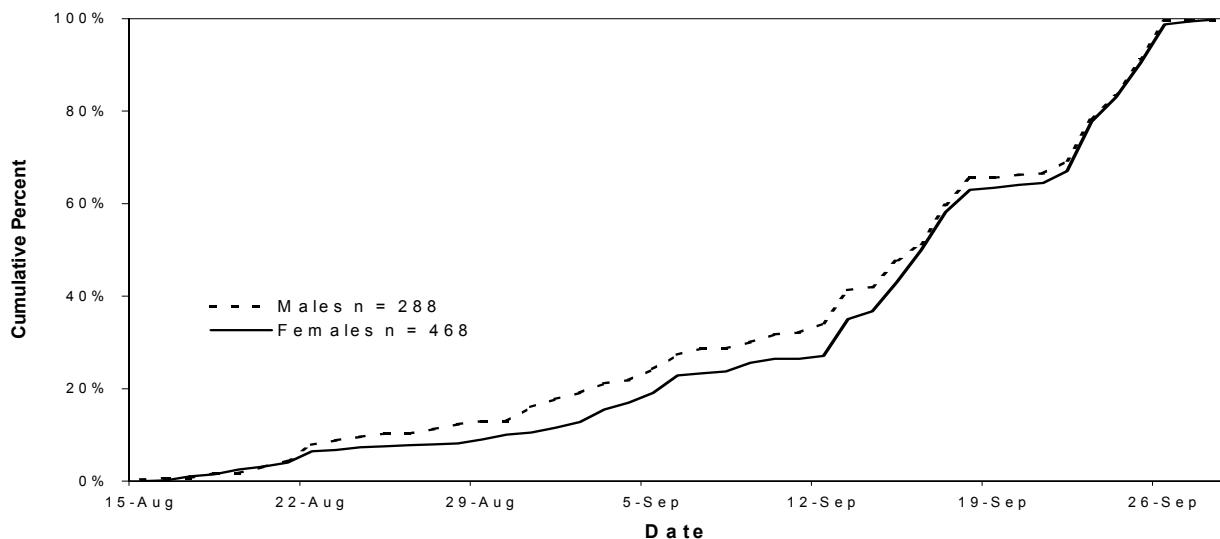

Figure 10. Daily cumulative percent of male and female steelhead.

4.7 Upper Sustut River and Tyee Test Fishery Indices

The 2001 upper Sustut steelhead population index and the cumulative Tyee test fishery index to August 10 were added to the historical regression relationship between these two values (Figure 11). With the addition of the new data point, the regression relationship was no longer statistically significant (ANOVA: $F=4.229$, $p=.0699$). As a result of the increased variability in the data (r^2 decreased from 0.3954 to 0.3197) the Tyee index can no longer be used as a predictor of upper Sustut steelhead abundance.

4.8 Steelhead Angling Selectivity

Between August 21 and September 14 a total of 16 steelhead were angled from a 1 km section of the upper Sustut River immediately downstream of the fence. One of these fish had been tagged at the fence (female, tag number 35188) on August 8 and subsequently overshot the fence remaining downstream

for the duration of the project. Ten of the angled steelhead (62.5%) were females and six (37.5%) were males (Appendix Table 8a). There was no

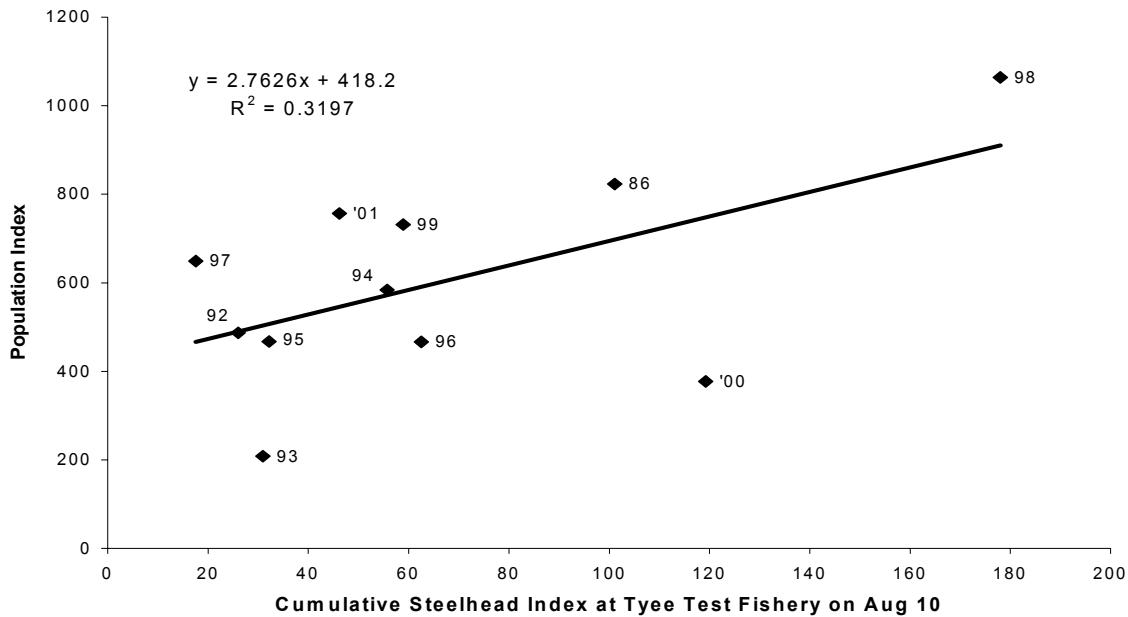

Figure 11. Linear relationship between the upper Sustut River steelhead population index and the cumulative steelhead index at the Tyee test fishery on August 10.

statistically significant difference between the sex ratio of the angled steelhead sample and the fence population ($\chi^2=0.0024$, $p=0.05$).

The nose-fork lengths of male steelhead in the angled sample ranged from 82.5 to 95.5 cm and averaged 86.8 cm. The nose-fork lengths of females in the angling sample ranged from 71.0 to 91.0 cm and averaged 78.0 cm (Appendix Table 8a). It was not possible to statistically compare the lengths of the angled sample and fence population due to the small size of the angled group.

The release condition of each angled fish was recorded after all sampling was complete. Of the 16 steelhead captured by angling, 13 (81.3%) swam away quickly on release (release condition 1), while three (18.7%) swam away slowly (release condition 2). No fish required ventilation at release.

Between September 6 and September 23 a total of 8 angled steelhead were recaptured at the fence. The recapture sample was made up of 3 males and 5 females representing 50.0 % of both angled males and females (Appendix Table 8b). Time between capture by angling and arrival at the fence ranged from 3 to 11 days for males and from 3 to 13 days for females. Average elapsed times were 7.0 days for males and 8.2 days for females (Appendix Table 8b) and were not statistically different (Students t-test: $t=0.3757$, $p<0.05$).

4.9 Steelhead Ages

The scales collected from the Sustut River were in excellent condition. As with the sample collected from Sustut River in 2000, all the adult steelhead exhibited at least two marine annuli, and repeat spawners made up 6.1% of the sample. The most prevalent age was 4.3+ (46.9%) followed by 4.2+ (24.5%) (Appendix Table 14a). The majority of the steelhead spent four years in freshwater (86.6%), while 6.7% had a three-year freshwater age, and 6.7% had a five-year freshwater age (Appendix Table 14b).

5.0 Discussion

The upper Sustut River steelhead population index for 2001 was 756 fish. This value is the second highest on record and almost 20% above the long term average (Table 1). One factor that may have influenced this result is the timing of steelhead arrival in the Skeena River. While commercial fisheries were once again extremely intense in the early portion of the fishing season the return timing of upper Sustut steelhead was later than normal. The date of 50% migration in 2001 was 9 days later than 2000 and was the second latest date on record (Table 1). One likely result of this deviation in migration timing may have been a lower than normal commercial fishery interception of the early Skeena steelhead stock complex including the upper Sustut population. With fewer fish captured incidentally in sockeye net fisheries, a greater number would successfully escape to spawning areas such as the upper Sustut River.

Favourable environmental conditions may also have impacted survival and total production. This is supported by the fact that 2001 saw the highest rate of potential repeat spawners on record (2001 = 2.5%; long term average = 1.3%) as well as the largest average nose-fork lengths for both males and females migrating past the fence (Parken *et al.* 1997; Williamson 1998, 1999a, 2000; Diewert 2000).

The mortality rate for steelhead handled at the fence in 2001 was 1.9% which was in the middle of the historical range (0 – 4.3%; Williamson 2000) but higher than those reported since 1997. Mortality rates have remained low since 1998 when personnel modified the fence by adding a covered recovery area for released steelhead and a low head baffle to reduce strandings on the fence at low water levels (Williamson, 1999b). While these modifications were implemented again in 2001, a new aluminum trap box was installed to replace the worn out plywood structure. It is likely that this new component contributed to elevated steelhead mortalities as a higher than average number of fish exhibited head abrasions and most of the mortalities were severely fungused in the head area. This may have resulted from fish rubbing their snouts on abrasive areas of the new trap.

Reports from previous years indicated that water temperature and river height influenced steelhead movement (Siamoto 1995; Parken and Morten 1996). Results from this year's study indicated that while environmental variables may partially influence steelhead migration past the fence, these factors were not significantly correlated with fish movement.

In 2001, 61.9 % of steelhead were female and 38.1 % were male yielding a ratio of 1.63:1 females to males. The skewed sex ratio in favour of females is similar to that found in previous years (Parken *et al.* 1997; Williamson 1998, 1999a, 2000; Diewert 2000). Parken *et al.* postulated that this may have resulted from disproportionate sampling throughout the run during early studies. However, since 1995 all steelhead have been identified to sex and therefore the reported sex ratios accurately reflect those of the population. Hooton has indicated (personal communication in Parken *et al.* 1997) that past research found males dominant in the beginning of the run and females dominant near the end of the run. This has not been the case in the upper Sustut during the past several years when females dominated throughout the run. It may be that gillnet fisheries targeting other species have selectively harvested male steelhead as their larger size and in some cases, secondary sexual characteristics, may make them more susceptible to this gear type.

A total of 12.8 % of all steelhead encountered at the fence exhibited gill net marks. This falls in the middle portion of historical values which have ranged from 2 to 23 % and averaged 11.7 % (Parken *et al.* 1997; Williamson 1998, 1999a, 2000; Diewert 2000). Female steelhead exhibited a higher gillnet mark rate than males (14.5 and 10.1 %, respectively). Further, gillnet marked males and females were significantly smaller than unmarked fish. This likely indicates that smaller fish (and therefore females) escape capture more often than larger fish due to the size selective nature of gillnets (Ricker 1975). The cumulative gillnet mark rate remained at zero to the end of August and then increased as the program progressed. This trend became more evident when the percent of gillnet marked steelhead was pooled and plotted by statistical week and may reflect the pattern of fishery openings, including in-river IFF and ESSR fisheries, which can result in different timing components of the run encountering more or fewer gillnets.

With the addition of the 2001 data point, the upper Sustut River steelhead population index was no longer significantly correlated with the cumulative Tyee test fishery index to August 10. As a result, the new data set no longer functions as a predictive relationship. This may be the result of recent adjustments made to commercial, IFF and ESSR fishing plans. Recent fisheries have been re-designed to target large Skeena sockeye returns while minimizing the impact on coho and the peak of the steelhead return. The resulting intensified effort during the early portion of the fishery coincides with the return migration of early summer run steelhead including the upper Sustut stock. This change in the intensity and timing of the fisheries has introduced additional variability into the regression relationship. Also, using the August 10 date as the Tyee test fishery index value may not adequately reflect the inter annual variation in early Skeena steelhead run timing. In years when early Skeena steelhead arrive later, the

cumulative Tyee index to August 10 may not include a significant portion of the run.

The sex ratio of the 16 steelhead captured in the angling survey was not statistically different from the sex ratio of the fence population. This result suggests that angling was not selective for males or females. However, as the angled sample was very small, this result should be viewed with caution.

A total of 50 % of the steelhead captured in the angling study migrated past the fence. This result suggests that angling placed a significant stress on captured fish. While the same proportion of angled males and females migrated upstream before the fence was removed and the average elapsed time between angling capture and fence arrival was similar for both sexes, sample sizes were extremely small. A past study revealed that females took longer to reach the fence and had a lower rate of successful migration past the fence indicating that angling may be more stressful for females (Diewert 2001). Future studies should continue to monitor post-angling behavior and make every effort to minimize stress while addressing sample size and other study design issues.

6.0 Recommendations

1. Enumeration of the upper Sustut River steelhead population should continue to be carried out annually. The valuable time series of data that results from this project provides fisheries managers with information on abundance trends for all early run Skeena steelhead populations. Sampling methods should continue as recommended by Parken and Morten (1996), thus maintaining the reliability of comparisons across years.
2. Efforts to visually enumerate steelhead below the fence prior to fence removal should continue. These counts provide the basis for estimating total escapement to the upper Sustut River. The survey should take as close to the date of fence removal as possible.
3. The relationship between the upper Sustut River steelhead population index and the Tyee test fishery index should continue to be investigated. With the addition of recent data the relationship is no longer statistically significant and therefore the cumulative Tyee test fishery index to August 10 can not be used to predict upper Sustut steelhead abundance. It is recommended that the data be re-examined to determine if additional factors (such as migration timing) could be included in the relationship to produce a new predictive model.
4. Fence modifications implemented in 1998 and described in Williamson (1999b), should continue to be utilized. It is also recommended that efforts be made to ensure that the new trap box is as fish friendly as possible by padding or smoothing off any areas of the structure that may cause abrasions to holding fish.

5. The placing of numerous sand bags along the bank has temporarily halted erosion at the fence site on river right. Planting willow branches in the streamside soil has encouraged the growth of riparian vegetation. However, these are temporary measures at best and further steps should be taken to stabilize this bank before the suitability of the present fence location is compromised. Also, stream bed erosion has occurred downstream of the fence sill. This scour trough continues to deepen each year. It is recommended that the effected area of the stream bed be filled and protected from further erosion with a suitable material.
6. If the angling selectivity study continues, it is recommended that the size of the angled sample be increased and that sampling be carried out proportionally throughout the duration of the run based on the migration rate past the fence.

7.0 Acknowledgments

Mike Whelpley, Andy Wanhill and Dominic McCosker provided technical support for the project. Ron Tetreau, Mark Beere, Paul Giroux, Jeff Lough and Ron Diewert helped with the installation of the fence. Ron Tetreau located recaptured steelhead in the TAGS database. Mark Beere, Paul Giroux and Cam Schley provided relief for the field crew during their mid project break. Ron Tetreau helped with the removal of the fence. The Steffey family provided a friendly and warm place to visit for the field crew. We thank Fisheries and Oceans Canada for loaning the travel trailer used in the field. Mark Beere provided editorial reviews and valuable comments for the final draft.

BC Conservation Foundation, Prince George, BC provided general contracting services.

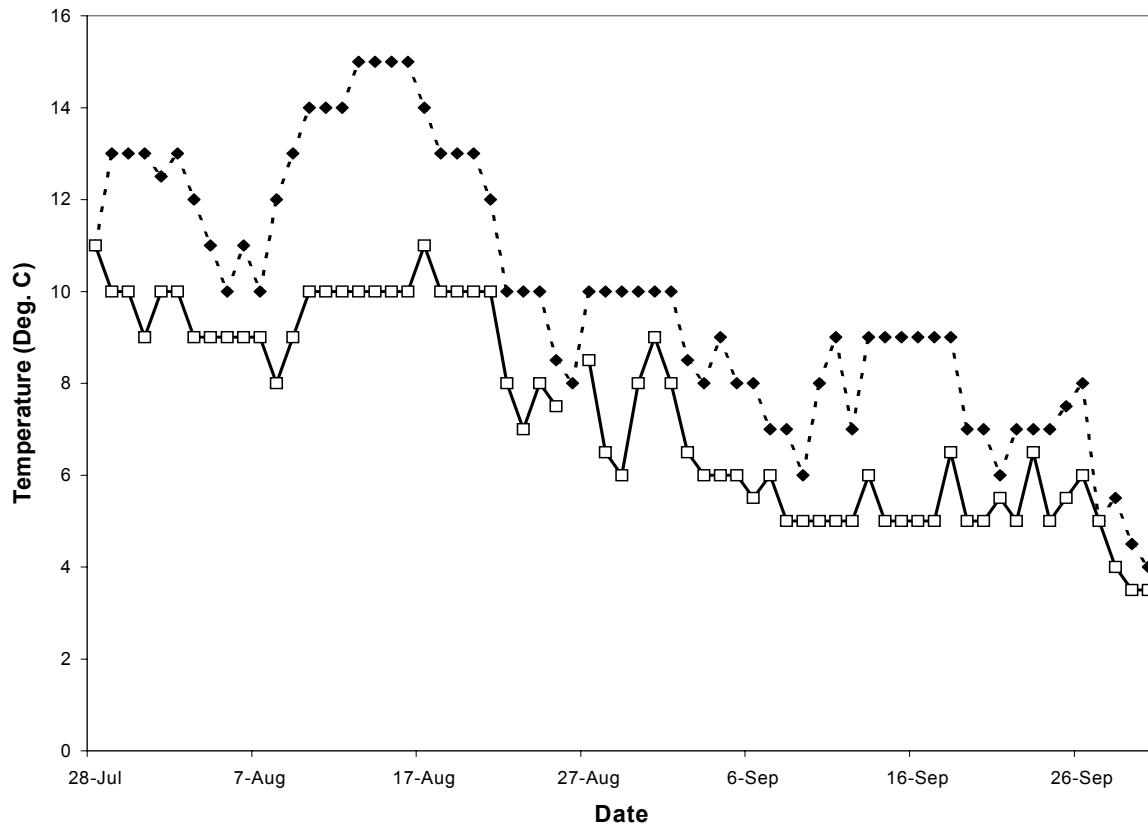

This project was funded by BC Environment's Habitat Conservation Trust Fund and was developed by personnel of BC Environment. The Habitat Conservation Trust Fund was created by an act of the legislature to preserve, restore and enhance key areas of habitat for fish and wildlife throughout British Columbia. Hunters, anglers, trappers and guides contribute to HCTF enhancement projects through license surcharges. Tax deductible donations to assist in the work of HCTF are welcome.

16-Sep-01	1730	M	65.0		spent
26-Sep-01	1900	M			spent

Appendix Table 13. Sampling data from all coho migrating past the Sustut River fence, 2001.

Date	Sex	Length (cm)		Scale Bk. Position	Scale Bk. Number	DNA	Comments
		Nose-Fork	P.O.H.				
15-Sep-01	M	71.5	56.5	1-41	40481	Vial #1	Good shape
21-Sep-01	M	64.0	48.5	2-42	40481	Vial #1	Abrasions left operc.
22-Sep-01	M	70.5	54.5	3-43	40481	Vial #1	Head abrasion
23-Sep-01	M	47.0				Vial #1	Jack; clean
23-Sep-01	F	68.5	65.0	4-44	40481	Vial #1	Clean
23-Sep-01	M	73.0	65.0	5-45	40481	Vial #1	Clean
23-Sep-01	F	62.0	48.0	6-46	40481	Vial #1	Clean
24-Sep-01	F	65.0	52.0	7-47	40481	Vial #1	Dorsal abrasion
24-Sep-01	M	66.0	51.0	8-48	40481	Vial #1	Scars and abrasions

Appendix Table 14a. Ages of steelhead sampled at the Sustut River fence, 2001, sorted by total marine age. Includes scales with regeneration for marine age.

Age	n	%	Total by Marine Age	
			n	%
3.2+	3	3.1%		
4.2+	24	24.5%		
5.2+	4	4.1%		
R.2+	4	4.1%	35	35.7%
3.3+	2	2.0%		
4.3+	46	46.9%		
5.3+	2	2.0%		
R.3+	5	5.1%	55	56.1%
4.4+	2	2.0%	2	2.0%
3.2S1+	1	1.0%		
4.2S1+	5	5.1%	6	6.1%
R.R+	2			
	98	100.0%	98	100.0%

Note: the R.R+ scale is not included in above percentages as it was not readable.

Appendix Table 14b. Ages of steelhead sampled at the Sustut River fence, 2001, sorted by total freshwater age. Excludes scales with regeneration for freshwater age.

Age	n	%	Total by Freshwater Age	
			n	%
3.2+	3	3.4%		
3.3+	2	2.2%		
3.2S1+	1	1.1%	6	6.7%
4.2+	24	27.0%		
4.3+	46	51.7%		
4.4+	2	2.2%		
4.2S1+	5	5.6%	77	86.5%
5.2+	4	4.5%		
5.3+	2	2.2%	6	6.7%
	89	100.0%	89	100.0%

Note: regenerated scales are not included in the above calculations
